

Paired-read support for TAC102 positional observations

Position	Both mates concordant	Both mates discordant	Dual-evidence pairs	Concordance	R1-only	R2-only
653	27	4	31	87.1%	105	101
698	20	2	22	90.9%	100	96

Paired-read concordance was assessed among read pairs for which both mates independently yielded positional evidence at the indicated TAC102 residue. Concordant pairs carried the same amino-acid call in both mates, whereas discordant pairs carried different calls. Dual-evidence pairs denote pairs in which both mates produced a validated positional observation. R1-only and R2-only counts represent read pairs for which positional evidence was recovered from only the indicated mate. Concordance percentages were calculated as the number of concordant pairs divided by the total number of dual-evidence pairs (concordant + discordant). Paired-read support provides independent mate-level evidence but does not by itself establish genomic fixation, zygosity, or population allele frequency.
